One Wire Driver for the PIC16F54 7 segments display

The Driver control the display over One Wire bus. The driver can set up the luminosity and shut-down the display. When the driver shutdown the display, the display can only be startup again from poweron or pushing the disable/enable-pin down.

The “PIC16F54 7 segments display”:

- 3 x 7 segments common cathode (5611AS)
- 1 x PIC16F54 Micro-Controller
- 3 x 2n7002 Transistors

Features

- One wire bus
- Disable/Enable Pin
- Dimming
- Sleep (Energy saving, Then you need two pins)
- 3 characters

Schematic

The schematic and the board files

One Wire Protocol

Bit Timing

The Timings have to be updated! Now the values are just fake values

Table 1: Bit Timing

Symbol	Description	Min	Typ	Max	Unit
EN	Enable	10	10	80	ms
TR	Time to read	90	100	110	ms
TN	Time to new bit	10	200	220	ms

EN Start of new bit

TR Time between start of EN and the remote sample the DIO

TN Time the remote spend wait for new Data, this should be bigger than the minimum allowed time for EN

Command Operation

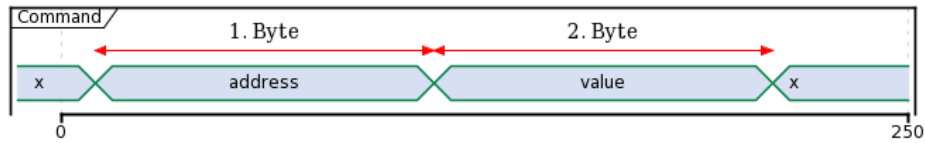

Figure 6: Command Operation

Registers

Adresse	Description	Default
0x00	Option	0x00
0x01	Digit 1	0x00
0x02	Digit 2	0x00
0x03	Digit 3	0x00

Option Register Bit Assignment

This register acts as setting register.

Table 3: Option Register

Option	7	6	5	4	3	2	1	0
	SLEEP	EN	DIM5	DIM4	DIM3	DIM2	DIM1	DIM0
Default	0	0	0	0	0	0	0	0

DIM<5-0> Dimmer, '0b000000' is full power and '0b111111' is dark.

EN Writing ‘1’ to this position will power off the segments. All segments are off, but the controller is still running.

SLEEP The controller go in sleep. Can only be restart push the MCLR pin down. All registers will be reset to theirs default value.

Digit x Register Bit Assignment

Registers describing the segments that should light on. Writing '1' to a position will light on this segments.

Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
DP	G	F	E	D	C	B	A

To-Do

- [x] Implement power off the segments (Bit 6 of option register)
- [] Update Bit-Timing with the right value
